

We will study the map for a pair of coupled PRCs. Let  $F(x)$  be the PTC and assume that  $F'(x) > 0$ ,  $F(0) = 0$ ,  $F(T) = T$

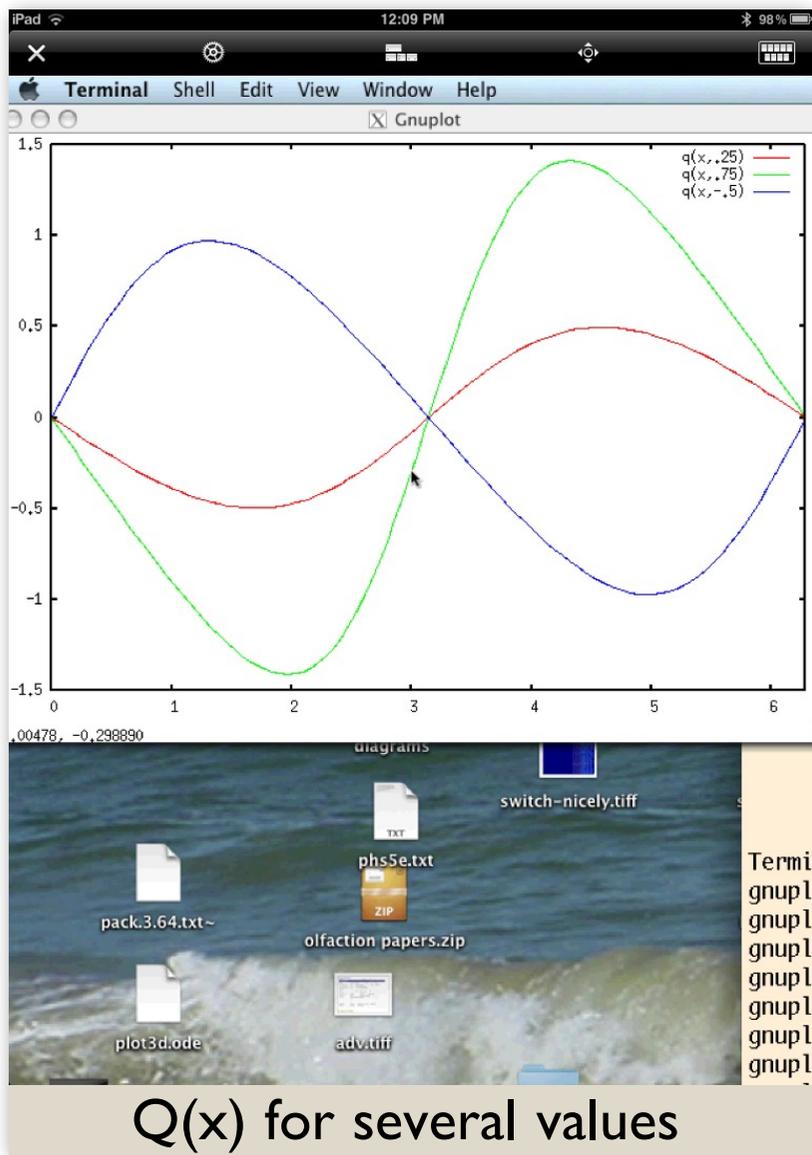

We will create a Poincare map for the time that oscillator B fires

Let  $y$  be the phase of B just as A hits T. Then  $B \rightarrow F(y)$  and  $A \rightarrow 0$ . Since  $F(y) < T$  as  $y < T$  and  $F'(x) > 0$ , oscillator B will not yet have fired. It takes  $T - F(y)$  time units for B to reach T since it has dynamics  $X' = 1$ . Thus, A which has the same dynamics advances to  $T - F(y)$  and is reset to  $F(T - F(y))$  while B is reset to 0. Thus, A will fire at  $T - F(T - F(y))$  and our map is thus

$$y' = T - F(T - F(y)) = G(y)$$

A fixed point,  $p$  satisfies  $p = G(p)$  and it is stable if  $|G'(p)| < 1$ . However, note that  $G'(p) = F'(T - F(p))F'(p)$  and by hypothesis,  $F'(*) > 0$ , so stability just means that  $G'(p) < 1$ . To see the fixed points, we need only plot  $Q(p) = G(p) - p$ , and the stable ones will be those for which  $Q'(p) < 0$ !

For example, let  $F(x) = x - b \sin(x)$ , where  $|b| < 1$ . Then  $T = 2\pi$  and it is clear that  $p = 0$  is a fixed point.  $G'(0) = (1 - b)^2 < 1$  if  $0 < b$ , so that we get stable dynamics when  $0 < b < 1$ . (Stability extends beyond  $b = 1$ , but that would violate our hypothesis on  $F'(x) > 0$ . Here is a picture of  $Q$  for three values

of  $b$ . Note that when  $b < 0$ , the fixed point at  $\pi$  is stable (blue curve).

HW.

1. Let the PRC be defined as  $-a \sin(x) - b \sin(2x)$  and the PTC  $F(x) = x - a \sin(x) - b \sin(2x)$

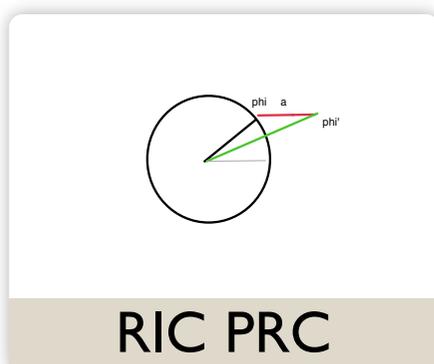

For what range of  $(a, b)$  is it true that  $F'(x) > 0$  for all  $x$  in  $[0, 2\pi]$ ? Plot  $Q(x)$  and find the fixed points and their stability for the following pairs  $(a, b)$ :  $(0.5, 0.2), (0.5, 0.4), (0.5, -0.2), (0.5, -0.4)$  Which cases have multiple stable fixed points?

2. Let  $F(x) = x + a(1 - \cos(x))$ . For what range of  $a$  is  $F'(x) > 0$ ? For  $a = 0.5$ , plot  $Q(x)$ . Are there any fixed points and

are they stable? With this PTC, is possible to stabilize a fixed point interior to  $(0, 2\pi)$ ?

3. Suppose that  $F(x) = x + c x^2(1 - x)$ , so that  $T = I$ . Study the fixed points of the composite map,  $G(x) = I - F(I - F(x))$  as a function of the parameter  $c$  and also figure out the range of  $c$  for which the hypothesis  $F'(x) > 0$  holds.

4. Recall the PTC for the radial isochron clock that you were asked to compute for homework.

$$\phi' = \text{atan}[\sin(\phi) / (a + \cos(\phi))] = F(\phi)$$

Using this map as your PTC, study the behavior of the composite map  $G(\phi)$  for  $a = 0.5, a = -0.5$ , and  $a = 1.25$ . You should be quite careful of how you define  $\text{atan}$ . You may want to use the numerical

function,  $\text{atan2}(y, x) = \text{atan}(y/x)$  where the signs of  $x$  and  $y$  are also considered.
